## 1. INTRODUCTION

Every non-negative integer $n$ has at least one digital expansion

$$
n=\sum_{k \geq 2} \epsilon_{k} F_{k}
$$

with digits $\epsilon_{k} \in\{0,1\}$. The maximal expansion with respect to the lexicographic order on $\left(\ldots, \epsilon_{4}, \epsilon_{3}, \epsilon_{2}\right)$ is the Zeckendorf expansion or, more generally, the greedy expansion, which has been studied by Zeckendorf [7] and many others. (Lexicographic order means (..., $\left.\epsilon_{3}, \epsilon_{2}\right)<$ $\left(\ldots, \epsilon_{3}^{\prime}, \epsilon_{2}^{\prime}\right)$ if $\epsilon_{k}<\epsilon_{k}^{\prime}$ for some $k \geq 2$ and $\epsilon_{j} \leq \epsilon_{j}^{\prime}$ for all $j \geq k$.) The minimal expansion with respect to this order is the less known lazy expansion, which was introduced by Erdős and Joó [4] (for $q$-ary expansions of $1,1<q<2$ ). For example, 100 has greedy expansion $100=89+8+3=F_{11}+F_{6}+F_{4}$ and lazy expansion $100=55+21+13+5+3+2+1=$ $F_{10}+F_{8}+F_{7}+F_{5}+F_{4}+F_{3}+F_{2}$. Denote the digits of the greedy expansion by $\epsilon_{k}^{g}(n)$ and those of the lazy expansion by $\epsilon_{k}^{\ell}(n)$.

The aim of this work is to study the structure of the possible digit sequences in order to obtain distributional results for the sum-of-digits functions

$$
s_{g}(n)=\sum_{k \geq 2} \epsilon_{k}^{g}(n) \text { and } s_{\ell}(n)=\sum_{k \geq 2} \epsilon_{k}^{\ell}(n)
$$

## 2. RESULTS

It is well known that Zeckendorf expansions have no two subsequent ones (because the pattern $(0,1,1)$ could be replaced by $(1,0,0))$ and that every finite sequence with no two subsequent ones is a Zeckendorf expansion of some integer (see Zeckendorf [7]). Symmetrically, lazy expansions have no two subsequent zeros preceeded by a one, because $(1,0,0)$ could be replaced by $(0,1,1)$, and it is not difficult to see that every such sequence is the lazy expansion of some integer (see Lemma 1).

For $s_{g}(n)$, Grabner and Tichy [5] proved (in the context of digital expansions related to linear recurrences) that its mean value is given by

$$
\frac{1}{N} \sum_{n<N} s_{g}(n)=\frac{1}{\alpha^{2}+1} \log _{\alpha} N+f_{1}\left(\log _{\alpha} N\right)+\mathcal{O}\left(\frac{\log N}{N}\right)
$$

where $f_{1}$ is periodic with period 1 , continuous and nowhere differentiable and $\alpha$ denotes the golden number $\frac{1+\sqrt{5}}{2}$. For the variance, Dumont and Thomas [2] obtained (in the more general context of numeration systems associated with primitive substitutions on finite alphabets)

$$
\frac{1}{N} \sum_{n<N}\left(s_{g}(n)-\frac{1}{\alpha^{2}+1} \log _{\alpha} N\right)^{2}=\frac{1}{5 \sqrt{5}} \log _{\alpha} N+f_{2}\left(\log _{\alpha} N\right) \log _{\alpha} N+o(1)
$$

where $f_{2}$ is again periodic with period 1 , continuous and nowhere differentiable. In [3], they showed that the distribution is asymptotically normal, i.e.

$$
\frac{1}{N} \#\left\{n<N \left\lvert\, \frac{s_{g}(n)-\frac{1}{\alpha^{2}+1} \log _{\alpha} N}{5^{-3 / 4} \sqrt{\log _{\alpha} N}}<x\right.\right\} \rightarrow \frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{x} e^{-t^{2} / 2} d t
$$

This is also a special case of a result of Drmota and Steiner [1], where generalizations of the sum-of-digits functions are studied.

The distribution of $s_{\ell}(n)$ has not been studied yet, but it is easy to replace the greedy expansions in [1] by lazy expansions and to obtain similar asymptotics (with expected value $\left.\frac{\alpha^{2}}{\alpha^{2}+1} \log _{\alpha} N\right)$. Instead of doing this, we will directly prove the following central limit theorem for the joint distribution of $s_{g}(n)$ and $s_{\ell}(n)$.
Theorem 1: We have, as $N \rightarrow \infty$,

$$
\begin{aligned}
\frac{1}{N} \#\left\{n<N \left\lvert\, \frac{s_{g}(n)-\mu_{g} \log _{\alpha} N}{\sigma \sqrt{\log _{\alpha} N}}<\right.\right. & \left.x_{g}, \frac{s_{\ell}(n)-\mu_{\ell} \log _{\alpha} N}{\sigma \sqrt{\log _{\alpha} N}}<x_{\ell}\right\} \\
& \rightarrow \frac{1}{2 \pi \sqrt{1-C^{2}}} \int_{-\infty}^{x_{\ell}} \int_{-\infty}^{x_{g}} e^{-\frac{1}{2\left(1-C^{2}\right)}\left(t_{g}^{2}+t_{\ell}^{2}-2 C t_{g} t_{\ell}\right)} d t_{g} d t_{\ell}
\end{aligned}
$$

with $\alpha=\frac{1+\sqrt{5}}{2}, \mu_{g}=\frac{1}{\alpha^{2}+1}, \mu_{\ell}=\frac{\alpha^{2}}{\alpha^{2}+1}, \sigma=5^{-3 / 4}$ and $C=9-5 \alpha \approx 0.90983$.
This means that the two sum-of-digits functions are strongly correlated. If one of them is large for some $n$, the probability of the other one to be large is very high. (The distribution is the Gaussian distribution with covariance matrix $\left(\begin{array}{ll}1 & C \\ C & 1\end{array}\right)$.)

Similarly to [1], corresponding results can be proved for $F$-additive functions, for sequences of primes and for polynomial sequences $P(n), n \in \mathbb{N}$, or $P(p), p \in \mathbb{P}$.

## 3. PROOFS

First we prove the characterization of lazy expansions given in Section 2.
Lemma 1: The lazy expansions are exactly those sequences $\left(\epsilon_{k}\right)_{k \geq 2} \in\{0,1\}^{\mathbb{N}}$ with $\left(\epsilon_{k}, \epsilon_{k-1}, \epsilon_{k-2}\right) \neq(1,0,0)$ for all $k \geq 4$ and only a finite number of $\epsilon_{k}=1$.

Proof: As already noted, the pattern $(1,0,0)$ does not occur because it could be replaced by $(0,1,1)$ and it suffices therefore to show that no two such sequences represent the same number. For an integer $n \in\left\{F_{k}-1, F_{k}, \ldots, F_{k+1}-2\right\}$, we must have $\epsilon_{j}^{\ell}(n)=0$ for all $j \geq k$ since $\epsilon_{j}^{\ell}(n)=1$ implies

$$
\sum_{i=2}^{j} \epsilon_{i}^{\ell}(n) F_{i} \geq F_{j}+F_{j-2}+F_{j-4}+\cdots=F_{j+1}-1
$$

On the other hand, we have $\epsilon_{k-1}^{\ell}(n)=1$ since the sum over all $F_{j}, 2 \leq j \leq k-2$, is

$$
\sum_{j=2}^{k-2} F_{j}=\left(F_{k-2}+F_{k-4}+\ldots\right)+\left(F_{k-3}+F_{k-5}+\ldots\right)=F_{k-1}-1+F_{k-2}-1=F_{k}-2
$$

and hence too small. The number of possible expansions with these properties is easily seen to be $F_{k-1}$ (by induction on $k$ ), thus equal to $\#\left\{F_{k}-1, F_{k}, \ldots, F_{k+1}-2\right\}$, and the lemma is proved.

In order to study the joint structure of the greedy and lazy digits, we show that

$$
D_{k}(n)=\sum_{j=2}^{k-1}\left(\epsilon_{j}^{\ell}(n)-\epsilon_{j}^{g}(n)\right) F_{j}=\sum_{j=k}^{\infty}\left(\epsilon_{j}^{g}(n)-\epsilon_{j}^{\ell}(n)\right) F_{j}
$$

can only take three values.
Lemma 2: $D_{k}(n), k \geq 3$, can only take the values $0, F_{k}$ and $F_{k-1}$.
Proof: We show that

$$
\begin{equation*}
\sum_{j \geq 3}\left(\epsilon_{j}^{\prime}-\epsilon_{j}^{\prime \prime}\right) F_{k}=\sum_{j \geq 2} \epsilon_{j} F_{j} \tag{1}
\end{equation*}
$$

with $\epsilon_{j}, \epsilon_{j}^{\prime}, \epsilon_{j}^{\prime \prime} \in\{0,1\}$ implies

$$
\begin{equation*}
\sum_{j \geq 3}\left(\epsilon_{j}^{\prime}-\epsilon_{j}^{\prime \prime}\right) F_{j+i}=\sum_{j \geq 2} \epsilon_{j} F_{j+i}-\delta F_{i} \tag{2}
\end{equation*}
$$

for all $i>0$ with $\delta \in\{0,1\}$. It suffices to prove (2) for $i=1$. Then the general equation follows by induction on $i$ with $F_{j+i}=F_{j+i-1}+F_{j+i-2}$.

Since $F_{j}$ is given by $F_{j}=\frac{1}{\sqrt{5}} \alpha^{j}-\frac{1}{\sqrt{5}}\left(-\frac{1}{\alpha}\right)^{j}$, we obtain

$$
F_{j+1}-\alpha F_{j}=\frac{1}{\alpha \sqrt{5}}\left(-\frac{1}{\alpha}\right)^{j}+\frac{\alpha}{\sqrt{5}}\left(-\frac{1}{\alpha}\right)^{j}=\left(-\frac{1}{\alpha}\right)^{j}
$$

Hence "(2) $-\alpha \times(1)$ " with $i=1$ yields

$$
-\delta=\sum_{j \geq 3}\left(\epsilon_{j}^{\prime}-\epsilon_{j}^{\prime \prime}-\epsilon_{j}\right)\left(-\frac{1}{\alpha}\right)^{j}-\epsilon_{2} \frac{1}{\alpha^{2}}
$$

and $\delta$ is bounded by

$$
-\delta<\frac{2}{\alpha^{3}}+\frac{1}{\alpha^{4}}+\frac{2}{\alpha^{5}}+\frac{1}{\alpha^{6}}+\cdots=\left(\frac{2}{\alpha^{3}}+\frac{1}{\alpha^{4}}\right) \frac{1}{1-\alpha^{-2}}=\frac{1}{\alpha} \alpha=1
$$

Since $\delta$ is an integer, we have thus $\delta \geq 0$. For the lower bound, we get

$$
-\delta>-\frac{1}{\alpha^{2}}-\frac{1}{\alpha^{3}}-\frac{2}{\alpha^{4}}-\frac{1}{\alpha^{5}}-\frac{2}{\alpha^{6}}-\cdots=-\left(\frac{2}{\alpha^{2}}+\frac{1}{\alpha^{3}}\right) \alpha+\frac{1}{\alpha^{2}}=-\alpha+\frac{1}{\alpha^{2}}=-1-\frac{1}{\alpha^{3}} .
$$

Hence $\delta \in\{0,1\}$ and (2) is proved. If either $\epsilon_{2}=0$ or $\epsilon_{j}=0$ for all $j \geq 4$, then we obtain $-\delta>-1$ and thus $\delta=0$.

Clearly we have

$$
\left|\sum_{j \geq k}\left(\epsilon_{j}^{g}(n)-\epsilon_{j}^{\ell}(n)\right) F_{j-k+3}\right|=\sum_{j \geq 2} \epsilon_{j} F_{j}
$$

for some $\epsilon_{j} \in\{0,1\}$, since the term on the left side is a non-negative integer. By (2), we get

$$
\left|D_{k}(n)\right|=\left|\sum_{j \geq k}\left(\epsilon_{j}^{g}(n)-\epsilon_{j}^{\ell}(n)\right) F_{j}\right|=\sum_{j \geq 2} \epsilon_{j} F_{j+k-3}-\delta F_{k-3}
$$

for all $k \geq 4$. Since $D_{k}(n)$ is bounded by

$$
\left|D_{k}(n)\right| \leq \sum_{j=2}^{k-1} F_{j}=F_{k+1}-2
$$

$\epsilon_{j}$ must be zero for all $j \geq 5$ and, if $\epsilon_{2}=1$, for $j \geq 4$. Hence we have $\delta=0, \epsilon_{j}$ must be zero for all $j \geq 4$ and the only possible values for $\left|D_{k}(n)\right|$ are $0, F_{k}$ and $F_{k-1}$.

Since greedy expansions have no two subsequent ones and lazy expansions have no two subsequent zeros (in the range of its ones), we have, for $k \geq 4$,

$$
D_{k}(n) \geq\left(F_{k-2}+F_{k-4}+\ldots\right)-\left(F_{k-1}+F_{k-3}+\ldots\right)=\left(F_{k-1}-1\right)-\left(F_{k}-1\right)=-F_{k-2}
$$

and thus $D_{k}(n) \geq 0$ if $\epsilon_{j}^{\ell}(n)=1$ for some $j \geq k$. Otherwise we have $\sum_{j=2}^{k-1} \epsilon_{j}^{\ell}(n) F_{j}=n$. Hence $D_{k}(n)$ is non-negative for $k \geq 4$. Clearly $\left|D_{3}(n)\right| \in\{0,1\}$ and $D_{3}(n)=D_{4}(n)-2\left(\epsilon_{3}^{\ell}(n)-\epsilon_{3}^{g}(n)\right)$. Because of $D_{4}(n) \in\{0,2,3\}, D_{3}(n)$ is non-negative and the lemma is proved.
Remark: $\delta$ in (2) can be 1, e.g. $F_{3}+F_{5}-F_{4}=F_{4}+F_{2}$ and $F_{4}+F_{6}-F_{5}=F_{5}+F_{3}-1$. This is due to $2 F_{k}=F_{k+1}+F_{k-2}$, but for $k=3$ we also have $2 F_{3}=F_{4}+F_{2}$.
Lemma 3: For $F_{K} \leq n \leq F_{K+1}-2$, the digits $\epsilon_{k}^{g}(n), \epsilon_{k}^{\ell}(n)$ have the following properties:

1. $\epsilon_{k}^{g}=0$ for all $k>K, \epsilon_{K}^{g}=1, \epsilon_{K-1}^{g}=0$
2. $\epsilon_{k}^{\ell}=0$ for all $k \geq K, \epsilon_{K-1}^{\ell}=1$
3. $\left(\epsilon_{k}^{g}, \epsilon_{k}^{\ell}\right)=(1,0)$ implies $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,1)$.
4. If $\left(\epsilon_{k+1}^{g}, \epsilon_{k+1}^{\ell}\right) \neq(0,1)$, then $\left(\epsilon_{k}^{g}, \epsilon_{k}^{\ell}\right)=(0,1)$ implies $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,1)$ with probability $\frac{F_{k-3}+1}{F_{k}-1}$ and $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,0),\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(1,1)$ with probabilities $\frac{F_{k-2}-1}{F_{k}-1}$.
5. If $\left(\epsilon_{k+1}^{g}, \epsilon_{k+1}^{\ell}\right)=(0,1)$, then $\left(\epsilon_{k}^{g}, \epsilon_{k}^{\ell}\right)=(0,1)$ implies $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(1,0)$ with probability $\frac{F_{k-2}-1}{F_{k-2}+1}$ and $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,0),\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(1,1)$ with probabilities $\frac{1}{F_{k-2}+1}$. In the latter cases, the $\left(\epsilon_{j}^{g}, \epsilon_{j}^{\ell}\right)$ are alternately $(0,0)$ and $(1,1)$ for $j<k$.
6. $\left(\epsilon_{k}^{g}, \epsilon_{k}^{\ell}\right)=(1,1)$ resp. $\left(\epsilon_{k}^{g}, \epsilon_{k}^{\ell}\right)=(0,0)$ imply $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,1)$, if the digits are not determined by 4. and $k<K$.

Proof: 1. is obvious and 2. follows from the proof of Lemma 1. Furthermore, these $n$ are the only integers with these properties (and their number is $F_{K-1}-1$ ). 3. follows directly
from the properties of greedy and lazy expansions. For the other properties, we use Lemma 2 and $D_{k-1}=D_{k}+\left(\epsilon_{k}^{g}-\epsilon_{k}^{\ell}\right) F_{k}$.

In 5., we must have $D_{k+2}=F_{k+2}, D_{k+1}=F_{k}$ and $D_{k}=0$. Hence $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)$ cannot be $(0,1)$. Furthermore, $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,0)$ implies $D_{k-1}=0$ and $\epsilon_{k-2}^{\ell}=1$. Thus $\epsilon_{k-2}^{g}=1$. Similarly $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(1,1)$ implies $\left(\epsilon_{k-2}^{g}, \epsilon_{k-2}^{\ell}\right)=(0,0)$. Inductively, we get the alternating sequence, i.e. only one possibility for the last digits. For $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(1,0)$, the situation is similar to that of $k-1=K$ and we have therefore $F_{k-2}-1$ possibilities. This gives the stated probabilities.

In 4., we must have $D_{k+1}=F_{k+1}$ and $D_{k}=F_{k-1}$. Then we have $F_{k-3}+1$ possibilities for $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,1)$ (see 5.). $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(1,1)$ and $\left(\epsilon_{k-1}^{g}, \epsilon_{k-1}^{\ell}\right)=(0,0)$ imply, with $D_{k-1}=F_{k-1},\left(\epsilon_{k-2}^{g}, \epsilon_{k-2}^{\ell}\right)=(0,1)$ and hence $F_{k-2}-1$ possibilities. This also proves 6 .
Remark: For $n=F_{K+1}-1$, the unique digital expansion is given by $\epsilon_{K-2 j}=1$ for all $j \leq K / 2-1$ and $\epsilon_{K-1-2 j}=0$ for all $j<K / 2-1$. Note that for these $n, s_{g}(n)$ is as large as possible whereas $s_{\ell}(n)$ is as small as possible (in the "neighbourhood" of $n$ ) while, for "typical" $n$, large $s_{g}(n)$ entails large $s_{\ell}(n)$.

Lemma 3 shows that we get simple transition probabilities from $\epsilon_{k}$ to $\epsilon_{k-1}$ if we exclude those $n$ whose digital expansions terminate by alternating $(1,1)$ 's and $(0,0)$ 's. Thus define the sets

$$
\mathcal{S}_{J, K}=\left\{n \in\left\{F_{K}, \ldots, F_{K+1}-1\right\} \mid\left(\epsilon_{k}^{g}(n), \epsilon_{k}^{\ell}(n)\right) \notin\{(0,0),(1,1)\} \text { for some } k \leq J\right\}
$$

for $K \geq J+3$. The number of excluded $n$ is

$$
\#\left(\left\{F_{K}, F_{K}+1, \ldots, F_{K+1}-2\right\} \backslash \mathcal{S}_{J, K}\right)=F_{K-J+1}
$$

(In case $\left(\epsilon_{J}^{g}, \epsilon_{J}^{\ell}\right)=(0,0)$, we have $F_{K-J}$ possibilities for $\epsilon_{J+1}^{g}, \ldots, \epsilon_{K-2}^{g}$, and in case $\left(\epsilon_{J}^{g}, \epsilon_{J}^{\ell}\right)=(1,1)$, we have $F_{K-J-1}$ possibilities for $\left.\epsilon_{J+2}^{g}, \ldots, \epsilon_{K-2}^{g}.\right)$

Define a sequence of random vectors $\left(X_{k, J, K}\right)_{k \geq 2}$ by

$$
\operatorname{Pr}\left[X_{k, J, K}=\left(b^{g}, b^{\ell}\right)\right]=\frac{1}{\# \mathcal{S}_{J, K}} \#\left\{n \in \mathcal{S}_{J, K} \mid \epsilon_{k}^{g}(n)=b^{g}, \epsilon_{k}^{\ell}(n)=b^{\ell}\right\}
$$

Lemma 3 shows that this is a Markov chain, i.e.

$$
\begin{aligned}
\operatorname{Pr}\left[X_{k-1, J, K}=\left(b_{k-1}^{g}, b_{k-1}^{\ell}\right) \mid X_{k, J, K}=\left(b_{k}^{g}\right.\right. & \left.\left., b_{k}^{\ell}\right), X_{k+1, J, K}=\left(b_{k+1}^{g}, b_{k+1}^{\ell}\right), \ldots\right] \\
= & \operatorname{Pr}\left[X_{k-1, J, K}=\left(b_{k-1}^{g}, b_{k-1}^{\ell}\right) \mid X_{k, J, K}=\left(b_{k}^{g}, b_{k}^{\ell}\right)\right]
\end{aligned}
$$

if we make a distinction between $X_{k+1, J, K}=(0,1)$ and $X_{k+1, J, K} \neq(0,1)$ in case $X_{k, J, K}=(0,1)$ (otherwise we had a Markov chain of order 2), say $X_{k, J, K}=(0,1)^{1}$ if $X_{k, J, K}=(0,1) \neq$ $X_{k+1, J, K}$ and $X_{k, J, K}=(0,1)^{2}$ if $X_{k, J, K}=(0,1)=X_{k+1, J, K}$.

The transition matrix $P_{k, J}$ defined by

$$
\left(\begin{array}{c}
\operatorname{Pr}\left[X_{k-1, J, K}=(0,0)\right] \\
\operatorname{Pr}\left[X_{k-1, J, K}=(0,1)^{1}\right] \\
\operatorname{Pr}\left[X_{k-1, J, K}=(0,1)^{2}\right] \\
\operatorname{Pr}\left[X_{k-1, J, K}=(1,0)\right] \\
\operatorname{Pr}\left[X_{k-1, J, K}=(1,1)\right]
\end{array}\right)=P_{k, J}\left(\begin{array}{c}
\operatorname{Pr}\left[X_{k, J, K}=(0,0)\right] \\
\operatorname{Pr}\left[X_{k, J, K}=(0,1)^{1}\right] \\
\operatorname{Pr}\left[X_{k, J, K}=(0,1)^{2}\right] \\
\operatorname{Pr}\left[X_{k, J, K}=(1,0)\right] \\
\operatorname{Pr}\left[X_{k, J, K}=(1,1)\right]
\end{array}\right)
$$

is, for $k \geq J+3$,

$$
P_{k, J}=\left(\begin{array}{ccccc}
0 & \frac{F_{k-2}-F_{k-J}}{F_{k}-F_{k-J}-J+2} & 0 & 0 & 0 \\
1 & 0 & 1 & 1 \\
0 & \frac{F_{k-3}-F_{k-J-1}}{F_{k}-F_{k-J+2}} & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & \frac{F_{k-2}-F_{k-J}}{F_{k}-F_{k-J+2}} & 0 & 0 & 0
\end{array}\right)=\left(\begin{array}{ccccc}
0 & \frac{1}{\alpha^{2}}+\mathcal{O}\left(\alpha^{-k}\right) & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 1 \\
0 & \frac{1}{\alpha^{3}}+\mathcal{O}\left(\alpha^{-k}\right) & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & \frac{1}{\alpha^{2}}+\mathcal{O}\left(\alpha^{-k}\right) & 0 & 0 & 0
\end{array}\right),
$$

i.e. the Markov chain is almost homogeneous. Denote the limit of this matrix for $k \rightarrow \infty$ by $P$. Its eigenvalues are $1,-\frac{1}{\alpha},-\frac{1}{\alpha^{2}}$ and 0 . Thus the probability distribution is almost stationary with

$$
\begin{aligned}
& \operatorname{Pr}\left[X_{k, J, K}=(0,0)\right]=\frac{1}{\alpha\left(\alpha^{2}+1\right)}+\mathcal{O}\left(\alpha^{-\min (k, K-k)}\right) \\
& \operatorname{Pr}\left[X_{k, J, K}=(0,1)^{1}\right]=\frac{\alpha}{\alpha^{2}+1}+\mathcal{O}\left(\alpha^{-\min (k, K-k)}\right) \\
& \operatorname{Pr}\left[X_{k, J, K}=(0,1)^{2}\right]=\frac{1}{\alpha^{2}\left(\alpha^{2}+1\right)}+\mathcal{O}\left(\alpha^{-\min (k, K-k)}\right) \\
& \operatorname{Pr}\left[X_{k, J, K}=(1,0)\right]=\frac{1}{\alpha^{2}\left(\alpha^{2}+1\right)}+\mathcal{O}\left(\alpha^{-\min (k, K-k)}\right) \\
& \operatorname{Pr}\left[X_{k, J, K}=(1,1)\right]=\frac{1}{\alpha\left(\alpha^{2}+1\right)}+\mathcal{O}\left(\alpha^{-\min (k, K-k)}\right)
\end{aligned}
$$

for $J<k<K$.
For a given $N=\sum_{k=2}^{L} \epsilon_{k}^{g}(N) F_{k}$ with $\epsilon_{L}^{g}(N)=1$ (i.e. $L \approx \log _{\alpha} N$ ), define

$$
\mathcal{S}_{N}=\bigcup_{k=L-\left[L^{\eta}\right]}^{L} \bigcup_{K=L-\left[L^{\eta}\right]}^{k-1}\left(\mathcal{S}_{\left[L^{\eta}\right], K}+\sum_{j=k+1}^{L} \epsilon_{j}^{g}(N) F_{j}\right)
$$

and a sequence of random vectors $\left(Y_{k, N}\right)_{k \geq 2}$ by

$$
\operatorname{Pr}\left[Y_{k, N}=\left(b^{g}, b^{\ell}\right)\right]=\frac{1}{\# \mathcal{S}_{N}} \#\left\{n \in \mathcal{S}_{N} \mid \epsilon_{k}^{g}(n)=b^{g}, \epsilon_{k}^{\ell}(n)=b^{\ell}\right\}
$$

This sequence is close to what we need because of

$$
\begin{equation*}
\#\left(\{0, \ldots, N-1\} \backslash \mathcal{S}_{N}\right)=\mathcal{O}\left(L^{\eta} F_{L-\left[L^{\eta}\right]}+L^{2 \eta} F_{L-2\left[L^{\eta}\right]}\right)=\mathcal{O}\left(\frac{(\log N)^{\eta} N}{\alpha^{\left(\log _{\alpha} N\right)^{\eta}}}\right) \tag{3}
\end{equation*}
$$

and, for $\left[L^{\eta}\right] \leq k \leq\left[L-L^{\eta}\right]$, the $Y_{k, N}$ are a Markov chain with transition matrices $P_{k,\left[L^{\eta}\right]}$. For $\left[L^{\eta}\right] \leq k \leq L-2\left[L^{\eta}\right]$, the distribution of $Y_{k, N}$ is thus almost stationary with the probabilities of $X_{k, J, K}$ and error terms $\mathcal{O}\left(\alpha^{-L^{\eta}}\right)$.

Lemma 4: The $Y_{k, N}=\left(Y_{k, N}^{g}, Y_{k, N}^{\ell}\right)$ satisfy a central limit theorem for $L^{\eta} \leq k \leq L-2 L^{\eta}$. More precisely, we have, for all $a_{g}, a_{\ell} \in \mathbb{R}$, as $N \rightarrow \infty$,

$$
\sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} \frac{a_{g}\left(Y_{k, N}^{g}-\mu_{g}\right)+a_{\ell}\left(Y_{k, N}^{\ell}-\mu_{\ell}\right)}{\sigma \sqrt{L}} \Rightarrow \mathcal{N}\left(0, a_{g}^{2}+a_{\ell}^{2}+2 a_{g} a_{\ell} C\right),
$$

where $\mathcal{N}(M, V)$ denotes the normal law with mean value $M$ and variance $V$.
Proof: For the mean value, we have

$$
\begin{aligned}
\mathbf{E} Y_{k, N}^{g} & =\operatorname{Pr}\left[Y_{k, N}^{g}=(1,0)\right]+\operatorname{Pr}\left[Y_{k, N}^{g}=(1,1)\right] \\
& =\frac{1}{\alpha^{2}\left(\alpha^{2}+1\right)}+\frac{1}{\alpha\left(\alpha^{2}+1\right)}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right)=\mu_{g}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right)
\end{aligned}
$$

and

$$
\mathbf{E} Y_{k, N}^{\ell}=\mu_{\ell}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right)
$$

Hence the mean value of the sum converges to zero. The variance is given by

$$
\begin{aligned}
& \operatorname{Var}\left(\sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} a_{g}\left(Y_{k, N}^{g}-\mu_{g}\right)+a_{\ell}\left(Y_{k, N}^{\ell}-\mu_{\ell}\right)\right) \\
& =\operatorname{Var} \sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} a_{g} Y_{k, N}^{g}+\operatorname{Var} \sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} a_{\ell} Y_{k, N}^{\ell}+2 \operatorname{Cov}\left(\sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} a_{g} Y_{k, N}^{g}, \sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} a_{\ell} Y_{k, N}^{\ell}\right) \\
& \quad=L \sigma^{2}\left(a_{g}^{2}+a_{\ell}^{2}\right)+\mathcal{O}\left(L^{\eta}\right)+2 a_{g} a_{\ell} \sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} \sum_{j=\left[L^{\eta}\right]-k}^{L-2\left[L^{\eta}\right]-k} \operatorname{Cov}\left(Y_{k, N}^{g}, Y_{k+j, N}^{\ell}\right) .
\end{aligned}
$$

(The calculation of the variance of $\sum Y_{k, N}^{g}$ and $\sum Y_{k, N}^{\ell}$ is similar to that in [1] and to that of the covariance hereafter.) The covariance is given by

$$
\operatorname{Cov}\left(Y_{k, N}^{g}, Y_{k+j, N}^{\ell}\right)=\operatorname{Pr}\left[Y_{k, N}^{g}=1, Y_{k+j, N}^{\ell}=1\right]-\operatorname{Pr}\left[Y_{k, N}^{g}=1\right] \operatorname{Pr}\left[Y_{k+j, N}^{\ell}=1\right] .
$$

For $j=0$, we obtain, with $\left(\alpha^{2}+1\right)^{2}=5 \alpha^{2}$,

$$
\operatorname{Cov}\left(Y_{k, N}^{g}, Y_{k, N}^{\ell}\right)=\frac{1}{\alpha\left(\alpha^{2}+1\right)}-\frac{\alpha^{2}}{\left(\alpha^{2}+1\right)^{2}}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right)=-\frac{1}{5 \alpha^{4}}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right) .
$$

The approximated transition matrix has the form $P=Q D Q^{-1}$

$$
\left(\begin{array}{ccccc}
\frac{1}{\alpha\left(\alpha^{2}+1\right)} & 1 & -\frac{\alpha^{3}}{\alpha^{2}+1} & 1 & 1 \\
\frac{\alpha}{\alpha^{2}+1} & -\alpha & \frac{\alpha^{3}}{\alpha^{2}+1} & 0 & 0 \\
\frac{1}{\alpha^{2}\left(\alpha^{2}+1\right)} & \frac{1}{\alpha} & -\frac{\alpha^{2}}{\alpha^{2}+1} & 0 & 0 \\
\frac{1}{\alpha^{2}\left(\alpha^{2}+1\right)} & -1 & \frac{\alpha^{4}}{\alpha^{2}+1} & -1 & -2 \\
\frac{1}{\alpha\left(\alpha^{2}+1\right)} & 1 & -\frac{\alpha^{3}}{\alpha^{2}+1} & 0 & 1
\end{array}\right)\left(\begin{array}{ccccc}
1 & 0 & 0 & 0 & 0 \\
0 & -\frac{1}{\alpha} & 0 & 0 & 0 \\
0 & 0 & -\frac{1}{\alpha^{2}} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{array}\right)\left(\begin{array}{ccccc}
1 & 1 & 1 & 1 & 1 \\
1 & -\frac{1}{\alpha} & -\alpha & 1 & 1 \\
1 & -\frac{1}{\alpha^{2}} & -\alpha^{2} & 1 & 1 \\
1 & 0 & 0 & 0 & -1 \\
0 & 0 & -\alpha & 0 & 1
\end{array}\right)
$$

and the transition matrix of order $j\left(P^{j}=Q D^{j} Q^{-1}\right)$ is given by

$$
\begin{aligned}
& P^{j}=\frac{1}{\alpha^{2}+1}\left(\begin{array}{ccccc}
\frac{1}{\alpha} & \frac{1}{\alpha} & \frac{1}{\alpha} & \frac{1}{\alpha} & \frac{1}{\alpha} \\
\alpha & \alpha & \alpha & \alpha & \alpha \\
\frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} \\
\frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} & \frac{1}{\alpha^{2}} \\
\frac{1}{\alpha} & \frac{1}{\alpha} & \frac{1}{\alpha} & \frac{1}{\alpha} & \frac{1}{\alpha}
\end{array}\right)+\left(-\frac{1}{\alpha}\right)^{j}\left(\begin{array}{ccccc}
1 & -\frac{1}{\alpha} & 1 & -\alpha & 1 \\
-\alpha & 1 & -\alpha & \alpha^{2} & -\alpha \\
\frac{1}{\alpha} & -\frac{1}{\alpha^{2}} & \frac{1}{\alpha} & -1 & \frac{1}{\alpha} \\
-1 & \frac{1}{\alpha} & -1 & \alpha & -1 \\
1 & -\frac{1}{\alpha} & 1 & -\alpha & 1
\end{array}\right) \\
&+\frac{1}{\alpha^{2}+1}\left(-\frac{1}{\alpha^{2}}\right)^{j}\left(\begin{array}{ccccc}
-\alpha^{3} & \alpha & -\alpha^{3} & \alpha^{5} & -\alpha^{3} \\
\alpha^{4} & -\alpha^{2} & \alpha^{4} & -\alpha^{6} & \alpha^{4} \\
\alpha^{3} & -\alpha & \alpha^{3} & -\alpha^{5} & \alpha^{3} \\
-\alpha^{2} & 1 & -\alpha^{2} & \alpha^{4} & -\alpha^{2} \\
-\alpha^{3} & \alpha & -\alpha^{3} & \alpha^{5} & -\alpha^{3}
\end{array}\right)
\end{aligned}
$$

Clearly

$$
\begin{aligned}
& \operatorname{Pr}\left[Y_{k, N}^{g}=1, Y_{k+j, N}^{\ell}=1\right] \\
= & \operatorname{Pr}\left[Y_{k+j, N}=(0,1)^{1}\right]\left(\operatorname{Pr}\left[Y_{k, N}=(1,0) \mid Y_{k+j, N}=(0,1)^{1}\right]+\operatorname{Pr}\left[Y_{k, N}=(1,1) \mid Y_{k+j, N}=(0,1)^{1}\right]\right) \\
& +\operatorname{Pr}\left[Y_{k+j, N}=(0,1)^{2}\right]\left(\boldsymbol{\operatorname { P r }}\left[Y_{k, N}=(1,0) \mid Y_{k+j, N}=(0,1)^{2}\right]+\mathbf{P r}\left[Y_{k, N}=(1,1) \mid Y_{k+j, N}=(0,1)^{2}\right]\right) \\
& +\operatorname{Pr}\left[Y_{k+j, N}=(1,1)\right]\left(\operatorname{Pr}\left[Y_{k, N}=(1,0) \mid Y_{k+j, N}=(1,1)\right]+\mathbf{P r}\left[Y_{k, N}=(1,1) \mid Y_{k+j, N}=(1,1)\right]\right) .
\end{aligned}
$$

Note that the contribution of the first matrix of $P^{j}$ to this probability is just $\mu_{g} \mu_{\ell}$ and that of the second matrix is zero. Hence we have, for $j>0$,

$$
\begin{aligned}
\operatorname{Cov}\left(Y_{k, N}^{g}, Y_{k+j, N}^{\ell}\right) & =\frac{1}{\alpha^{2}+1}\left(-\frac{1}{\alpha^{2}}\right)^{j}\left(\frac{\alpha(1+\alpha)}{\alpha^{2}+1}+\frac{-\alpha^{2}-\alpha^{3}}{\alpha^{2}\left(\alpha^{2}+1\right)}+\frac{-\alpha^{2}-\alpha^{3}}{\alpha\left(\alpha^{2}+1\right)}\right)+\mathcal{O}\left(\alpha^{-L^{\eta}}\right) \\
& =-\frac{1}{5}\left(-\frac{1}{\alpha^{2}}\right)^{j}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right)
\end{aligned}
$$

For $j<0$, we get similarly

$$
\operatorname{Cov}\left(Y_{k, N}^{g}, Y_{k-|j|, N}^{\ell}\right)=-\frac{1}{5}\left(-\frac{1}{\alpha^{2}}\right)^{|j|}+\mathcal{O}\left(\alpha^{-L^{\eta}}\right) .
$$

Therefore we have

$$
\begin{aligned}
& \sum_{j=\left[L^{\eta}\right]-k}^{L-2\left[L^{\eta}\right]-k} \operatorname{Cov}\left(Y_{k, N}^{g}, Y_{k+j, N}^{\ell}\right) \\
& \quad=-\frac{1}{5}\left(\frac{1}{\alpha^{4}}+2 \sum_{j=1}^{\infty}\left(-\frac{1}{\alpha^{2}}\right)^{j}\right)+\mathcal{O}\left(L \alpha^{-L^{\eta}}\right)+\mathcal{O}\left(\alpha^{-2 \min \left(k-\left[L^{\eta}\right], L-2\left[L^{\eta}\right]-k\right)}\right)
\end{aligned}
$$

With

$$
C=-\frac{1}{5 \sigma^{2}}\left(\frac{1}{\alpha^{4}}+2 \sum_{j=1}^{\infty}\left(-\frac{1}{\alpha^{2}}\right)^{j}\right)=-\frac{\alpha^{2}+1}{\alpha}\left(\frac{1}{\alpha^{4}}-\frac{2}{\alpha^{2}+1}\right)=9-5 \alpha
$$

we obtain

$$
\operatorname{Var}\left(\sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} a_{g}\left(Y_{k, N}^{g}-\mu_{g}\right)+a_{\ell}\left(Y_{k, N}^{\ell}-\mu_{\ell}\right)\right)=L \sigma^{2}\left(a_{g}^{2}+a_{\ell}^{2}+2 a_{g} a_{\ell} C\right)+\mathcal{O}\left(L^{\eta}\right) .
$$

We apply the central limit theorem for Markov chains or mixing sequences (e.g. Theorem 2.1 of Peligrad [6]) and the lemma is proved.

Because of (3), we have

$$
\begin{aligned}
\frac{1}{N} \#\{n<N & \left.\left\lvert\, \frac{s_{g}(n)-\mu_{g} \log _{\alpha} N}{\sigma \sqrt{\log _{\alpha} N}}<x_{g}\right., \frac{s_{\ell}(n)-\mu_{\ell} \log _{\alpha} N}{\sigma \sqrt{\log _{\alpha} N}}<x_{\ell}\right\} \\
& \rightarrow \frac{1}{\# \mathcal{S}_{N}} \#\left\{n \in \mathcal{S}_{N} \left\lvert\, \frac{s_{g}(n)-\mu_{g} \log _{\alpha} N}{\sigma \sqrt{\log _{\alpha} N}}<x_{g}\right., \frac{s_{\ell}(n)-\mu_{\ell} \log _{\alpha} N}{\sigma \sqrt{\log _{\alpha} N}}<x_{\ell}\right\} \\
& \rightarrow \frac{1}{\# \mathcal{S}_{N}} \#\left\{n \in \mathcal{S}_{N} \left\lvert\, \sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} \frac{\epsilon_{k}^{g}(n)-\mu_{g}}{\sigma \sqrt{L}}<x_{g}\right., \sum_{k=\left[L^{\eta}\right]}^{L-2\left[L^{\eta}\right]} \frac{\epsilon_{k}^{\ell}(n)-\mu_{\ell}}{\sigma \sqrt{L}}<x_{\ell}\right\}
\end{aligned}
$$

With Lemma 4, the theorem is proved.
