#### Problems to address

Extension of PQ Type inference Imperative style Parameter-state distinction

## Background

**Definition.** An *n*-qubit state  $\psi$  is a unit vectors in the  $2^n$  dimensional complex Hilbert space  $\mathbf{H}_n = (\mathbb{C}^{2^n}, \langle -|-\rangle).$ 

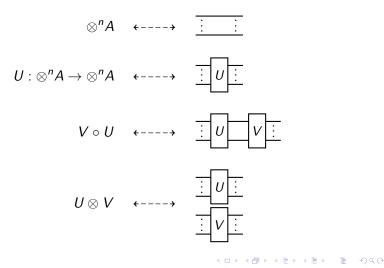

**Definition.** An *n*-qubit gate is a unitary operator U on  $H_n$ .

**Definition.** An *n*-qubit measurement *M* is given by a finite family  $\{S_i\}_i$  of operators satisfying  $\sum_{i \in I} S_i^{\dagger} S_i = I$ . When performing the measurement *M* on a quantum state  $\varphi \in \mathbf{H}_n$ , one of the measurement outcomes  $i \in I$  will be observed with probability  $P(i) = ||S_i\varphi||^2$ , and the state will be changed to  $\frac{S_i\psi}{\sqrt{P(i)}}$ .

## Quantum circuit

**Definition.** Quantum circuits are string diagrams for symmetric monoidal groupoid [Joyal and Street, 1991].

A useful abstract model of a quantum computer is the so-called  $\underline{\text{QRAM model}}$  [Knill, 1996]. In this model, we assume to have access to *N* numbered qubits, and be able to perform operations:

- prepare qubit *i* in state  $|0\rangle$  or  $|1\rangle$ .
- apply *n*-qubit gates to *n* distinct qubits  $i_1, i_2, ..., i_n$ .
- measure qubit i.

## Untyped lambda calculus

Definition. Lambda terms

 $M, N ::= x \mid MN \mid \lambda x.M$ 

where x ranges over an infinite set of symbols called variables.

**Example.**  $\lambda x.x$  is a lambda term. It stands for the identity function.  $(\lambda x.xy)(\lambda y.yz)$  is a lambda term. x is <u>bound</u>, z is <u>free</u>, and the variable y has both a free and a bound occurrence.

 Alpha equivalence — terms differ only in the choice of bound variables are considered the same.

• <u>Beta reduction</u> —  $(\lambda x.M)N \rightarrow M[N/x]$ .

## Simply Typed lambda calculus

**Definition.** Types  $S, T ::= B \mid S \rightarrow T$ , where B ranges over a set of symbols called basic types.

**Example.** *B* and  $B \rightarrow B$  are types.  $B \rightarrow B$  is a function type.

**Definition.** A type assignment  $\Gamma$  is a function from some finite set of variables to types.  $\Gamma$  is written as  $\{x : A, y : B, ...\}$ .

**Definition.** A typing judgement is a triple  $(\Gamma, M, T)$  of a type assignment, a term, and a type, written in the form  $\Gamma \vdash M : T$ .

## Typing rules

# **Definition.** A typing judgement is <u>valid</u> if it follows from typing rules:

$$\frac{x : A \in I}{\Gamma \vdash x : A}$$

$$\frac{\Gamma \vdash M : A \to B \quad \Gamma \vdash N : A}{\Gamma \vdash MN : B}$$

$$\frac{\Gamma, x : A \vdash M : B}{\Gamma \vdash \lambda x \cdot M : A \to B}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

## Propositional logic

**Definition.** Formulas (only the implication fragment)

 $S, T ::= B \mid S \rightarrow T$ ,

where B ranges over a set of atomic propositions.

**Definition.** A sequent is a pair  $(\Gamma, A)$ , written as  $\Gamma \vdash A$ , where  $\Gamma$  is a finite multiset of formulas, called a <u>context</u>, and A is a formula. We have three natural ways (derivations) to prove a formula.

$$\frac{A \in \Gamma}{\Gamma \vdash A} \qquad \frac{\Gamma \vdash A \to B \quad \Gamma \vdash A}{\Gamma \vdash B} \qquad \frac{\Gamma, A \vdash B}{\Gamma \vdash A \to B}.$$

## Curry-Howard correspondence

Curry-Howard correspondence [Curry, 1934, Howard, 1995].

- formulas  $\leftrightarrow$  types (if atomic propositions  $\leftrightarrow$  basic types).
- well-typed lambda terms  $\leftrightarrow$  derivations.

Recall definitions: Types  $S, T ::= B \mid S \to T$ , where B ranges over basic types. Formulas  $S, T ::= B \mid S \to T$ , where B ranges over atomic propositions.

#### Proofs-as-terms

**Example.** Let  $\Gamma = \{A, B\}$ , we have two derivations of *B*:

$$\frac{B \in \Gamma}{\Gamma \vdash B} \qquad \qquad \frac{A \in \Gamma}{\frac{\Gamma \vdash A}{\Gamma \vdash A \to B}}$$

Label assumptions  $\Gamma = \{x : A, y : B\}$ , and put lambda terms in:

$$\frac{y: B \in \Gamma}{\Gamma \vdash y: B} \qquad \qquad \frac{\frac{x: A \in \Gamma}{\Gamma \vdash x: A}}{\frac{\Gamma \vdash x: A}{\Gamma \vdash \lambda x. y: A \to B}} \frac{\frac{y: B \in \Gamma}{\Gamma, x: A \vdash y: B}}{\Gamma \vdash \lambda x. y: A \to B}$$

### Quantum lambda calculus

**Definition.** The types of Quantum Lambda Calculus (QLC) [Valiron, 2004] are defined by

 $A,B ::= \top | bit | qubit | A \multimap B | A \otimes B | !A.$ 

Definition. The terms of QLC are defined by

U ranges over a given set of symbols called <u>circuit constants</u>, and q ranges over a given infinite set of symbols called quantum names.

#### Type system

**Definition.** We define a relations <: on types, called subtyping relations satisfying ...

$$\frac{|A| <: B_1 \quad A_2 <: B_2}{|A| <: A} \quad \frac{|A| <: B_1 \quad A_2 <: B_2}{|A| <: A_1 <: A_2 <: (B_1 \otimes B_2)} \otimes$$

**Definition.** A typing judgement is a quadruple  $\Gamma$ ;  $Q \vdash M : T$ , where  $\Gamma$  is a type assignment, Q is a finite set of quantum names, called <u>quantum context</u>, M is a term, and T is a type. A typing judgement is valid if it follows from ...

$$\frac{\Gamma, x: A; Q \vdash M: B}{\Gamma; Q \vdash \lambda x.M: A \multimap B} \lambda_1 \qquad \frac{!\Delta, x: A; \emptyset \vdash M: B}{!\Delta; \emptyset \vdash \lambda x.M: !(A \multimap B)} \lambda_2$$

#### **Operational semantics**

**Definition.** A quantum closure is a triple [Q, L, M] where

- Q is an n-qubit state.
- *L* is a list of *n* distinct quantum names, written as  $|q_1q_2...q_n\rangle$ .
- M is a QLC term.

**Definition.**  $[Q, L, M] \rightarrow_p [Q', L', M']$  is a single-step reduction of quantum closures that takes place with probability p. Some reduction rules:

$$\begin{split} & [Q, |q_1, \dots, q_n\rangle, U\langle q_{j_1}, \dots, q_{j_n}\rangle] \to_1 [Q', |q_1, \dots, q_n\rangle, \langle q_{j_1}, \dots, q_{j_n}\rangle] \\ & [\alpha |Q_0\rangle + \beta |Q_1\rangle, |q_1, \dots, q_n\rangle, \text{ meas } q_i] \to_{|\alpha|^2} [Q_0, |q_1, \dots, q_n\rangle, 0] \\ & [Q, |q_1, \dots, q_n\rangle, \text{ new } 0] \to_1 [Q \otimes |0\rangle, |q_1, \dots, q_n, q_{n+1}\rangle, q_{n+1}] \end{split}$$

## Proto-Quipper

**Definition.** The types of Proto-Quipper (PQ) [Ross, 2015] are defined by

 $A,B ::= \dots | Circ(T,U)$ where  $T,U ::= \top | qubit | T \otimes U.$ 

**Definition.** The terms of PQ are defined by M, N, P ::= ...

| (t, C, M) | rev | unbox | box<sup>T</sup> | q

where  $t, u ::= * | q | \langle t, u \rangle$ . Here, C ranges over a set  $\mathbb{C}$  of <u>circuit constants</u>.

Type system of PQ is similar to the one of QLC.

- Almost the same subtyping rules as in QLC.
- One more typing rule

$$\frac{|\Delta; Q_1 \vdash t : T \quad |\Delta; Q_2 \vdash M : U \quad ln(C) = Q_1 \quad Out(C) = Q_2}{|\Delta, \emptyset \vdash (t, C, M) : Circ(T, U)} circ$$

## Labelled quantum circuit

**Definition.** Consider the category  $\mathbb{LC}$  with objects finite sequences of distinct quantum names, and morphisms between  $\langle q_1, q_2, ..., q_n \rangle$  and  $\langle p_1, p_2, ..., p_n \rangle$  are quantum circuits. We call the morphisms labelled quantum circuits.

- ▶ Partial tensor. If two objects s<sub>1</sub> and s<sub>2</sub> are disjoint (seen as sets), define s<sub>1</sub> ⊗ s<sub>2</sub> = s<sub>1</sub>, s<sub>2</sub>. The tensor product of morphisms is just the tensor product of labelled quantum circuits.
- Partial composition. The purpose of partial composition D ∘' C is to append circuit D to C, when dom(D) ≠ cod(C).

## Partial compostition

#### Example.

・ロト ・聞ト ・ヨト ・ヨト

æ.

#### **Operational semantics**

**Definition.** A circuit closure is a pair [C, M] where

- C is a labelled quantum circuit.
- M is a lambda term.

**Definition.** The one-step reduction relation, written as  $\rightarrow$ , is defined on circuit closures by rules such as

$$[C, rev (i, D, o)] \rightarrow [C, (o, D^{-1}, i)]$$

$$\frac{s \in Obj(\mathbb{LC}) \quad len(s) = len(T) \quad t = Term(s, T)}{[C, box^{T}(M)] \rightarrow [C, (t, Id_{s}, Mt)]} box$$

$$\frac{b = bind(V, u) \quad b' = bind(dom(D), cod(D))}{[C, (unbox(u, D, u'))V] \rightarrow [D \circ' (b \circ' C), b'(u')]} unbox$$

## Problems

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

## Extension of PQ

- PQ extends a minimal version of QLC. How to incorporate additional features of the QLC in PQ, such as coproducts, recursion, and measurement.
- We will extend the notion of quantum circuit to also include classical wires, which hold a classical bit at circuit execution time.
- It is no longer the case that all circuits are reversible. It will be necessary to extend the type system to be aware of this fact.

## Type inference

- Valiron described [Valiron, 2004] a type inference algorithm for QLC.
- Type inference is useful because it is tedious for programmers to write type annotations.
- But it is not known whether it can be done efficiently.
- An interesting open problem is to find efficient type inference algorithm for QLC and/or PQ.

#### Imperative style

A typical quantum program reads

let 
$$(x, y) = Cnot(x, y)$$
 in  
let  $y = Hy$  in  
let  $(y, x) = subroutine(y, x)$  in  
 $(x, y)$ 

In Quipper, we can use a simpler 'imperative style'

```
Cnot(x,y);
Hy;
subroutine(y,x);
```

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

No theoretical foundation for such a syntax yet.

### Imperative style

It gets complicated when

- Functions produce 'garbage' (ancilla qubits to hold intermediate results of the computation).
- Function have some imperative and some non-imperative arguments. For example,

let 
$$x' = Cnot(x, y)$$
.

Functions are in the body of loops.

loop 10 ( 
$$\lambda \langle x, y \rangle$$
 .let  $x = H x$  in  $\langle x, y \rangle$  ).

#### Parameter-state distinction

Consider a circuit defined on n qubits, such as the  $QFT_n$ 

It would be natural to define a circuit family as a lambda term

$$QFT$$
:  $(n: Nat) \multimap \otimes^n qubit \multimap \otimes^n qubit.$ 

But this requires dependent types.

- In QFT<sub>n</sub>, n is a parameter that is known when generating circuit.
- In Hq, q refers to a quantum state that is known when executing the circuit H.
