# AN INTERESTING SEQUENCE OF FIBONACCI SEQUENCE GENERATORS 

JOSEPH J. HEED<br>Norwich University, Northfield, Vermont 05663<br>and<br>LUCILLE KELLY<br>Vermont College, Montpelier, Vermont 05666

An observation that certain sequences of power residues modulo some primes were generalized Fibonacci sequences led to the investigation of the positive sequence with general term $n^{2}-n-1$. This sequence was found to have some interesting properties.
For example,

$$
3^{k} \equiv 3^{k-1}+3^{k-2}(\bmod 5), \quad 4^{k} \equiv 4^{k-1}+4^{k-2}(\bmod 11),
$$

$\left\{5^{k}\right\}$ is similarly defined $\bmod 19$, etc. If we take as initial values $1, n$, and define a Fibonacci sequence based on these values, the $r^{\text {th }}$ term is given by $n f_{r-1}+f_{r-2}$, where $f_{r}$ is the $r^{\text {th }}$ Fibonacci number. It is then a simple matter to show that $n^{2}-n-1$ divides $n^{r}-n f_{r-1}-f_{r-2}$. Thus,

$$
\begin{gathered}
n^{k} \equiv n^{k-1}+n^{k-2}\left(\bmod n^{2}-n-1\right) . \\
\text { THE SEOUENCE }\left\{n^{2}-n-1\right\}
\end{gathered}
$$

1. Let $m(n)=n^{2}-n-1$. Let $p$ be prime, and let $p \mid m(N)$. Then there is a unique partition of $p, p=a+b$, such that $p \mid m(N+k p)$ and $p \mid m(N+k p+a)$.
i. That $p \mid m(N+k p)$ is easily verified
ii. $p \mid m(N+k p+a)$

$$
m(N+k p+a)=N^{2}+2 N k p+2 N a+k^{2} p^{2}+2 k p a+a^{2}-N-k p-a-1 .
$$

This is divisible by $p$ if $p \mid 2 N+a-1$.
There is some smallest value of $a$ for which this is true, and this value of $a$ is independent of $N$. For let $p \mid m(n)$ $n \neq N$. Then $p \mid m\left(N+k p+a^{\prime}\right)$ for $a^{\prime}$ such that $p \mid 2 n+a^{\prime}-1$.
Thus,

$$
p k^{\prime}=a-1+2 N, \quad p k^{\prime \prime \prime}=a^{\prime}=1+2 n .
$$

Subtracting and adding:

$$
p k^{\prime \prime}=\left(a^{\prime}-a\right)+2(n-N) \quad \text { and } \quad p k^{*}=a+a^{\prime}+2(N+n-1) .
$$

Since

$$
p \mid N^{2}-N-1 \quad \text { and } \quad p \mid n^{2}-n-1,
$$

then

$$
p \mid\left(N^{2}-N-1\right)-\left(n^{2}-n-1\right),
$$

that is, $p \mid(N-n)(N+n-1)$.
Either $p \mid N-n$ or $p \mid N+n-1$.
In the former instance it follows that $p \mid a^{\prime}-a$, and since both are less than $p, a=a^{\prime} . \operatorname{In}$ the latter case $p \mid a+a^{\prime}$, and $a+a^{\prime}=p$, that is, $a^{\prime}=b$.
2. If $p \mid m(N)$, then $p \mid m(N-b)$.

$$
m(N-b)=m(N)+b(b-2 N+1) .
$$

But

$$
b-2 N+1=p-a-2 N+1=p-(a-1+2 N), \quad \text { and } \quad p \mid(a-1+2 N) .
$$

3. If a prime $p$ appears as a factor in the sequence it does appear at these regular intervals of $a$ and $b$, and only then. For let

$$
\begin{gathered}
p|m(N), \quad p| m(N+a) \quad \text { and } \quad p \mid m(N+a+x), \quad a+x \leqslant p \\
m(N+a+x)=m(N+a)+x(2 N+a-1)+(a+x)
\end{gathered}
$$

Since $p \mid m(N+a)$ and $p \mid 2 N+a-1, p$ must divide $a+x$. But this is possible only if $p=a+x$, and $x=b$.
4. Let
$m(N)=p_{1}^{r_{1}} p_{2}^{r_{2}} \cdots p_{t}^{r_{t}}$,
$p_{i}$ prime, $t>1$. We have $N^{2}>m(N)>(N-1)^{2}$. No $p \stackrel{1}{=} N$, for if $m(N)=p \cdot Q$ with $p=N$, we have

$$
Q=N-1-\frac{1}{N}
$$

which is impossible. Thus some $p<N$. But in that event $N-p>0$ and $p \mid m(N-p)$, yielding: if $p \mid m(N)$, then

$$
p=m(N) \text { or } p \mid m(n)
$$

for some $n<N$.
5. All factors of $m(N)$ terminate in 1,5 or 9 . The period for $m(N)$ modulo 10 is $1,5,1,9,9$. The product of such elements terminates in 1,5 or 9 . Since $N^{2}>m(N)$, at most one $p$ can exceed $N$, and by (4) at most one prime factor new to the sequence can be introduced per term. If we assume for $n<k$ all factors terminate in 1,5 or 9 , and if $m(N)=p \cdot Q$ for $N \geqslant k$, with $p$ a new factor, then since $Q$ terminates in 1,5 or 9 so must $p$.
6. Further, it is true that every prime of the form $10 n \pm 1$ is a member of the sequence.
i. First we establish that 5 is a quadratic residue of every prime of the form $10 n \pm 1$. If $p$ is an odd prime $(p \neq 5)$, then by the Law of Quadratic Reciprocity,

$$
\left(\frac{5}{p}\right)\left(\frac{p}{5}\right)=(-1)^{\frac{5-1}{2} \cdot \frac{p-1}{2}}=+1
$$

Thus $(p / 5)=(5 / p)$, and if 5 is a quadratic residue of $p, p$ is also a quadratic residue of 5 , that is, $5 \mid x^{2}-p$ for some $x$. It is easily verified that $p \equiv \pm 1 \bmod 10$.
ii. There are two incongruent solutions to $x^{2}-5 \equiv 0 \bmod p, z$ and $p-z$. One is odd, the other even. Let $z$ be odd, and let $N=(z+1) / 2$.

$$
N^{2}-N-1=1 / 4\left(z^{2}-5\right) . \quad p\left|z^{2}-5 \quad \therefore p\right| N^{2}-N-1
$$

7. An examination of the sequence reveals an unexpected number of terms which are prime. However, this situation cannot be expected to continue. It is known that primes of the form $10 n \pm 1$ and $10 n \pm 3$ are equinumerous [1], and that $\sum 1 / p, p$ prime, diverges.

$$
\sum_{n=2}^{\infty} 1 / n^{2}-n-1
$$

converges, as must the subseries consisting of terms which are prime. The implication being, terms, $n^{2}-n-1$, which are prime must become rarer as $n$ increases.
